Testing legacy code: Hard-wired dependencies

Code related to testing legacy code with hard wired dependencies.

See the blog post from Sandro Mancuso: [Testing legacy code: Hard-wired dependencies](#). Try not reading the blog post before doing the exercise yourself.

What is it about?

Provides an example of existing code that needs to be unit tested and refactored. Currently no test are available.

There is one rule:

We can't change any existing code if not covered by tests. The only exception is if we need to change the code to add unit tests, but in this case, just automated refactorings (via IDE) are allowed.

Although this is a very small piece of code, it has a lot of the problems that we find in legacy code.

Details

If you want to give it a go, the starting point is [TripServiceTest.java](#) and [TripService.java](#). Try unit testing it following the rule above. Start refactoring, when the code is covered by tests.

Imaging a social network side for travelers:

- You need to be logged in to see content
- You can see the trips from your friends

For future comparisons, when you are done, you can always check [TripService_Original.java](#)

You can watch an example on YouTube: <https://www.youtube.com/watch?v=NnEIPO5BU0>
